

# Water treatment II

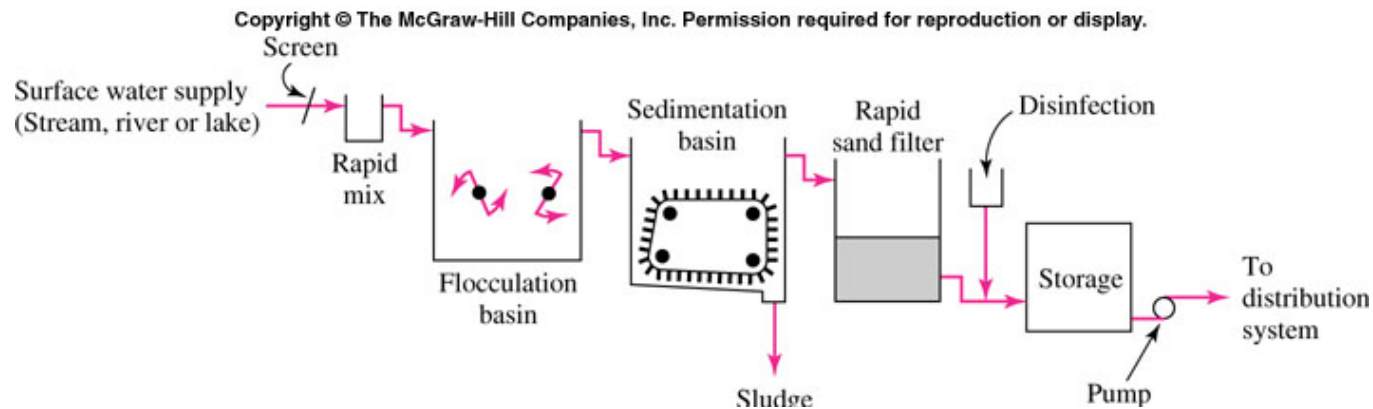

# Today's lecture

---

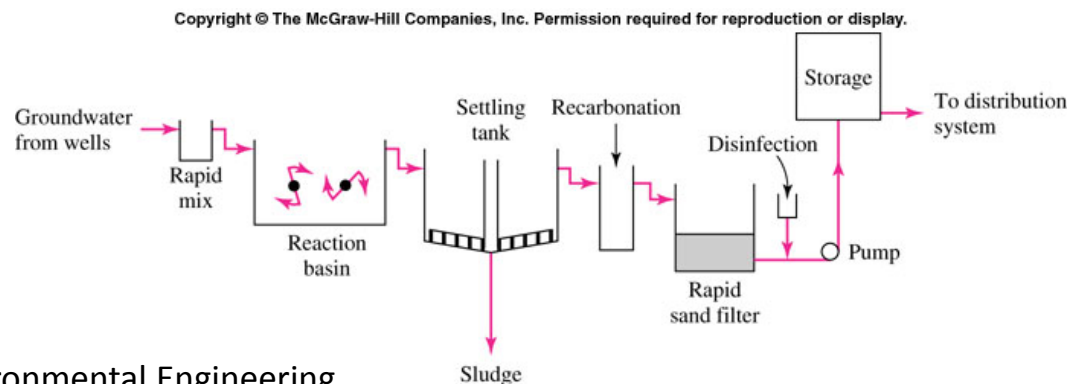

- Sedimentation
- Filtration
- Disinfection
- Chlorine disinfection chemistry
- Membrane processes
- Sludge treatment and disposal

# Water treatment systems

- Coagulation plant (surface water)

- Water softening plant (groundwater)

# Sedimentation

---

- Sedimentation basins: (a) rectangular (b) circular

(b)

Weir

# Sedimentation

---

- Design parameters

- Retention (detention) time: 2-4 hr

- Overflow rate,  $v_o$

$$v_o = \frac{Q}{A_c}$$

$Q$  = water flow rate (m<sup>3</sup>/s)

$A_c$  = surface area of the sedimentation basin (m<sup>2</sup>)

- Weir loading ( $WL$ )

$$WL = \frac{Q}{L_{weir}}$$

$L_{weir}$  = weir length (m)

- \* Large, dense particles: better settling properties

- higher  $v_o$  and  $WL$  allowed

# Filtration

---

- The effluent of the sedimentation basin still contains particles that are too small to settle
- Filtration is the final step of particle removal from water
- Goal: turbidity and pathogen removal
  - Pathogens are small particles (virus: 5-50 nm, bacteria: 0.5-10  $\mu\text{m}$ , protozoa oocysts: 2-20  $\mu\text{m}$ )
- Water flows downward through a bed of granular media, and particles in water are trapped by the media

# Filtration

---

- As particles are removed, filter becomes clogged → “head loss” increases → water becomes harder to pass the filter & effluent turbidity increases
- “Backwash” of filter needed (takes about 10-15 min, about once per day)

- Backwash
  - Water flow upward at a high speed to expand the media
  - Particles are washed out and collected

<http://www.rpi.edu>

# Filtration

---

- Filter media
  - Single media: sand only
  - Dual media: anthracite coal and sand (most common)
  - Multimedia: anthracite coal, sand, and garnet
- Large, lighter particles on the top and small, heavier particles on the bottom → can use full depth of the filter bed & maintain the layers after backwashing

Material	Grain density (g/cm <sup>3</sup> )	Effective size (mm)
Anthracite coal	1.6-1.7	1.5-2.5
Sand	2.4-2.6	0.6-0.95
Garnet	4.5	0.4-0.5

# Disinfection

---

- Goal: to inactivate (kill) pathogens
- Disinfection kinetics

– Chick's law:

$$\frac{dN}{dt} = -kN \longrightarrow \ln\left(\frac{N}{N_0}\right) = -kt$$

$N$  = number of organisms  
 $k$  = first-order reaction constant

– Chick-Watson law: consider the concentration of the disinfectant as a variable

$$\ln\left(\frac{N}{N_0}\right) = -k'C^n t$$

$k = k'C^n$   
 $C$  = disinfectant concentration, mg/L  
 $n$  = coefficient

→ The efficiency of disinfection depends on disinfectant concentration ( $C$ ) and contact time ( $t$ )

# Disinfection

---

- Goal: to inactivate (kill) pathogens by 99-99.9% (2-3 log removal)
- What is the appropriate reactor design?

Chlorine disinfection

UV disinfection

# Types of disinfectants

---

Disinfectant	Advantage	Disadvantage
Chlorine (Cl <sub>2</sub> )	<ul style="list-style-type: none"> <li>• Effective for most microorganisms</li> <li>• leaves residual</li> </ul>	<ul style="list-style-type: none"> <li>• Forms disinfection byproducts</li> <li>• Not effective to some protozoa</li> <li>• Taste and odor problem</li> </ul>
Chloramine	<ul style="list-style-type: none"> <li>• More stable residual than chlorine</li> <li>• Less disinfection byproduct than chlorine</li> </ul>	<ul style="list-style-type: none"> <li>• Less effective than chlorine</li> </ul>
Ozone	<ul style="list-style-type: none"> <li>• Very powerful</li> <li>• Effective for most microorganisms, including protozoa</li> </ul>	<ul style="list-style-type: none"> <li>• Must be produced on-site</li> <li>• Forms disinfection byproducts</li> <li>• No residual</li> </ul>
UV	<ul style="list-style-type: none"> <li>• Effective for bacteria &amp; protozoa</li> <li>• No disinfection byproducts</li> </ul>	<ul style="list-style-type: none"> <li>• Less effective for some viruses</li> <li>• No residual</li> <li>• Effectiveness affected by turbidity</li> </ul>

# Disinfection byproducts

---

- Disinfectants may react with  $\text{Br}^-$  or naturally occurring organic matter to make disinfection byproducts (DBPs)
- Some DBPs are known or possible human carcinogens
- Major DBPs
  - Chlorine disinfection: trihalomethanes (THMs), haloacetic acids (HAAs)
  - Ozone disinfection: bromate ( $\text{BrO}_3^-$ )
- Balance needed for disinfectant dose!
  - Disinfectant dose  $\uparrow$ , then pathogen kill  $\uparrow$ , but disinfection byproduct  $\uparrow$

# Disinfection byproducts

---

Does swimming do **good** or **bad** for your health??

# Chlorine disinfection chemistry

---

- Chlorine may be added to water as  $\text{Cl}_2$ ,  $\text{NaOCl}$ , or  $\text{Ca(OCl)}_2$
- Large plants mostly use  $\text{Cl}_2$
- $\text{Cl}_2$  rapidly reacts with water to form  $\text{HOCl}$ :  
$$\text{Cl}_2(g) + \text{H}_2\text{O} \rightleftharpoons \text{HOCl} + \text{H}^+ + \text{Cl}^-$$
- $\text{HOCl}$  is a weak acid that dissociates to form  $\text{OCl}^-$  with a  $pK_a$  of 7.54 at 25°C:  
$$\text{HOCl} \rightleftharpoons \text{H}^+ + \text{OCl}^-$$
- Both  $\text{HOCl}$  and  $\text{OCl}^-$  can kill pathogens, but  $\text{HOCl}$  is much stronger

# Chlorine disinfection chemistry

---

**Q:** So, for chlorine disinfection, would you prefer high pH ( $\text{pH} > 7.54$ ) or low pH ( $\text{pH} < 7.54$ )?

# Chlorine disinfection

---

- Factors affecting chlorine disinfection
  - Dosage
  - Contact time
  - Turbidity: the presence of particles (turbidity) hides the pathogen from disinfectant – this is one of the reason why we remove particles!
  - Other reactive species: some substances in water can consume chlorine (ex: ammonia)
  - pH: effective at  $\text{pH} < 7.5$
  - Water temperature: temperature  $\uparrow$ , then pathogen kill rate  $\uparrow$ , but chlorine stability  $\downarrow$

# Membrane processes

- Getting more and more popular
- Opening size: microfiltration > ultrafiltration > nanofiltration > reverse osmosis

# Sludge treatment & disposal

---

- Large amount of sludge (=mass of settled solids) is produced during the water treatment because of the addition of coagulants or lime
- Major goal of sludge treatment: removing as much water as possible
- When appropriate sludge treatment is accomplished, the sludge is disposed in the landfill

Sludge in the sedimentation basin
