Chapter 3-2: Programs

Soo-Ik Chae

High Performance Embedded Computing

Topics

Program performance analysis.

Varieties of performance metrics

- Worst-case execution time (WCET):
 - □ Factor in meeting deadlines.
 - Schedulability
- Average-case execution time:
 - Load balancing, etc.
 - To find hot spot
- Best-case execution time (BCET):
 - Factor in meeting deadlines.

High Performance Embedded Computing

Performance analysis techniques

- Simulation.
 - Not exhaustive.
 - Cycle-accurate CPU models are often available.
- WCET analysis.
 - Formal method; may make use of some simulation techniques.
 - Bounds execution time but hides some detail.

WCET analysis approach

- Path analysis + path timing
- Path analysis determines worst-case execution path.
- Path timing determines the execution time of a path.
- The two problems interact somewhat.

High Performance Embedded Computing

Performance models

- Simple model --- table of instructions and execution times.
 - Ignores instruction interactions, data-dependent effects.
- Timing accident: a reason why an instruction takes longer than normal to execute.
- Timing penalty: amount of execution time increase from a timing accident.

SW estimation overview: approaches

High Performance Embedded Computing

System-level software model

- Must be fast whole system simulation
- Processor model must be cheap
 - "what if" my processor did X
 - future processors not yet developed
 - evaluation of processor not currently used
- Must be convenient to use
 - no need to compile with cross-compilers
 - debug on my desktop
- Must be accurate enough for the purpose

Accuracy vs Performance vs Cost

	Accuracy	Speed	\$\$\$*
Hardware Emulation	+++	+ -	
Cycle accurate model	++		
Cycle counting ISS	++	+	-
Dynamic estimation	+	++	++
Static spreadsheet	-	+++	+++

*\$\$\$ = NRE + per model + per design

High Performance Embedded Computing

Program path analysis

Basic blocks

- A basic block is a program segment which is only entered at the first statement and only left at the last statement.
- Example: function calls
- The WCET (or BCET) of a basic block is determined
- A program is divided into basic blocks
 - Program structure is represented on a directed program flow graph with basic blocks as nodes.
 - A longest / shortest path analysis on the program flow identify WCET / BCET

Program path analysis Program path analysis Determine extreme case execution paths. Avoid exhaustive search of program paths. for (i=0; i<100; i++) {</pre> if (rand() > 0.5)2¹⁰⁰ possible j++; worst case else paths! k++; Eliminate False Paths: Make use of path information provided by the user. if (ok) i = i*i + 1; 🔨 else Always i = 0;executed if (i) together! j++; else j = j*j; High Performance Embedded Computing 11

Program path analysis: structural constraints

 Linear constraints constructed automatically from program's control flow graph.

High Performance Embedded Computing

Program path analysis: functional constraints

- Provide loop bounds (mandatory).
- Supply additional path information (optional).

Path timing

- Includes processor modeling:
 - Pipeline state.
 - Cache state.
- Also includes loop iteration bounding.
 - Loops with conditionals, data-dependent bounds create problems.

High Performance Embedded Computing

WCET bound vs. measured bound

Cache behavior and timing

- Cache affects instruction fetch time.
 - Time depends on state of the cache.
- Li and Malik break the program into units of cache lines.
 - Each basic block constitutes one or more I-blocks that correspond to cache lines.
 - Each I-block has hit, miss execution times.
 - Cache conflict graph models states of the cache lines.

High Performance Embedded Computing

Direct mapped Instruction caches

- the code in basic blocks are divided into a number of line-blocks
- the line blocks are assigned to cache lines
 - cache sets (cache lines) represent physical cache memory

Grouping Instructions: Line-blocks

- Line-block (I-block) = Basic block \cap Cache line
 - » All instructions within a I-block have same cache hit/ miss counts.

High Performance Embedded Computing

19

Adding cache analysis to the ILP model

 Now execution times of basic blocks differ if the lineblocks are in the cache or not

$$Execution_time = \sum_{i=1}^{N} \sum_{j=1}^{n_i} \left(C_{i,j}^{hit} \chi_{i,j}^{hit} + C_{i,j}^{miss} \chi_{i,j}^{miss} \right)$$

$$i = \text{ all basic blocks}$$
the execution count of a basic block becomes
$$x_i = x_{i,j}^{hit} + x_{i,j}^{miss}$$

$$j = 1,2... \text{ ni}$$

$$i = \text{ all basic blocks}$$

$$i = \text{ all basic blocks in block } i$$

$$i = \text{ all basic blocks in block } i$$

$$j = \text{ all basic blocks in block } i$$

$$x_{i} = x_{i,j}^{hit} + x_{i,j}^{miss}$$

$$x_{i} = x_{i,j}^{miss} = x_{i,j}^{miss} + x_{i,j}^{miss}$$

$$x_{i} = x_{i,j}^{miss} + x_{i,j}^{miss}$$

Cache constraints

- There are three possible types of cache assignments that can occur
 - Only one line-block assigned to a cache line
 - when a miss occurs, the line-block will be loaded and no more cache misses will occur

 $x_{kl}^{miss} \leq 1$

- Two or more *nonconflicting* line-blocks are assigned to the same cache line
 - when a miss occurs in either block, the line-blocks will be loaded and no more cache misses will occur

 $x_{1.3}^{miss} + x_{2.1}^{miss} \le 1$

a cache line contains two or more conflicting line-blocks

High Performance Embedded Computing

21

Cache Conflict Graph

Capture control flow of I-blocks mapping to the same cache line only.

Cache conflict graphs

- s and e nodes represents the start and the end of the program respectively
- B nodes represent conflicting line-blocks
- Edges represent possible program flow between blocks
 - acquired from program cfg
- p(node1, node2) is a counter associated with each edge

High Performance Embedded Computing

Constraints on cache conflict graphs

- The counters (p) are bound to the structural and functional constraints trough the x variables
 - the execution count of a line-block must be equal to the execution count of the basic block
 - the control flow to a line-block node must be equal to the flow from the line-block node

$$x_i = \sum_{u.v} p(u.v, i.j) = \sum_{u.v} p(i.j, u.v)$$

Constraints from CCG

Flow at node *B*_{*k*,*l*}:

 $x_{k} = p(s,kl) + p(m.n,k.l) + p(k.l,k.l)$ = p(k.l,e) + p(k.l,m.n) + p(k.l,k.l)

Cache hit count for *I-block* B_{k.l}:

$$p_{(k,l,k,l)} \leq x_{k,l}^{hit} \leq p_{(s,k,l)} + p_{(k,l,k,l)}$$

Starting Condition: $p_{(s,kl)} + p_{(s,mn)} + p_{(s,e)} = 1$

High Performance Embedded Computing

Implementation - `cinderella'

- ~15,000 lines C++ code
- WWW page: http://www.princeton.edu/~yauli/ cinderella

Experimental Results

Path Timing

- Several techniques are used to analyze path timing at different levels of abstraction.
- Abstract interpretation: to understand the execution states of the program
- Data flow analysis: a more detailed view of how the program behaves
- Simulation: the most concrete technique

Healy et al. loop iteration bounding

- Use an iterative algorithm to identify branches that affect loop termination.
- Identifies the loop iteration on which those branches change direction.
- Determine whether these branches are reached.
- Calculate iteration bounds.

Thieling et al. abstract interpretation

- Executes a program using symbolic values.
 - Allows behavior to be generalized.
 - Concrete state is full state; abstract state is one-to-many onto the concrete state.
- Cache behavior may be analyzed using abstract state.
 - Must analysis looks at upper bounds of memory block ages.
 - May analysis looks at lower bounds.
 - Persistence analysis looks at behavior after first access.
