Inequality constrained minimization

Consider minimization

min
$$f_0(x)$$

s.t. $f_i(x) \le 0, i = 1, ..., m,$ (1)
 $Ax = b,$

where $f : \mathbb{R}^n \to \mathbb{R}$ is convex and twice cont. diff'ble (hence domain is open) and $A \in \mathbb{R}^{p \times n}$ is of full row-rank. We also assume \exists optimal solution $x^* \in \text{dom} f$ such that $p^* = f(x^*)$. Furthermore, a Slater type constraint qualification holds: \exists feasible x satisfying $f_i(x) < 0 \forall i = 1, ..., m$. From KKT conditions, a point $x^* \in D$ is optimal iff $\exists \lambda^*$ and ν^* such that

$$Ax^{*} = b, f_{i}(x^{*}) \leq 0, \quad i = 1, ..., m$$

$$\lambda^{*} \geq 0,$$

$$\nabla f_{0}(x^{*}) + \sum_{i=1}^{m} \lambda_{i}^{*} \nabla f_{i}(x^{*}) + A^{T} \nu_{*} = 0,$$

$$\lambda_{i}^{*} \nabla f_{i}(x^{*}) = 0, \quad i = 1, ..., m.$$
(2)

伺 ト イ ヨ ト イ ヨ ト

Logarithmic barrier

Minimization (1) can be rewritten as follows:

$$\min_{f_0(x)} f_0(x) + \sum_{i=1}^m I_-(f_i(x))$$
s.t. $Ax = b,$
(3)

where I_{-} is indicator for the nonpositive reals:

$$I_{-}(u) = \begin{cases} 0, & \text{for } u \leq 0, \\ \infty, & \text{for } u > 0. \end{cases}$$

As an approximation of indicator, we can use logarithmic barrier,

$$\hat{l}_{-}(u) = -(1/t)\log(-u), \ \operatorname{dom}\hat{l}_{-} = -\mathbb{R}_{++},$$
 (4)

where t > 0 is a parameter that sets the accuracy of approximation: the larger, the more accurate.

- 4 同 6 4 日 6 4 日 6

Logarithmic barrier(*cont'd*)

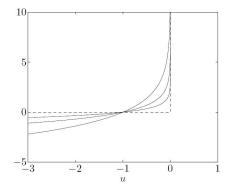

Figure 11.1 The dashed lines show the function $I_{-}(u)$, and the solid curves show $\widehat{I}_{-}(u) = -(1/t)\log(-u)$, for t = 0.5, 1, 2. The curve for t = 2 gives the best approximation.

A 10

A B > A B >

Thus (3) is approximated by

The term

$$\phi(x) = -\sum_{i=1}^m \log(-f_i(x)),$$

with dom $\phi = \{x \in \mathbb{R}^n : f_i(x) < 0, i = 1, ..., m\}$, is called the *logarithmic* barrier or log barrier of (1).

- Notice (5) is convex since $-(1/t)\log(-u)$ is convex and increasing in u.
- Thus, with an appropriate closedness, Newton's method, for instance, can be used to solve it.

・ 同 ト ・ ヨ ト ・ ヨ ト ・ ヨ

- Quality of (5) as approximation of (1) improves as t grows as will be seen.
- On the other hand, lager t makes minimization of $f_0 + (1/t)\phi$ via Newton's method difficult as Hessian varies rapidly near boundary of feasible region.
- This can be circumvented by solving a sequence of (5), increasing t at each iteration, starting at the solution of the previous t.

Logarithmic barrier(cont'd)

KKT conditions of log barrier approximation (5) and central path

Consider following equivalent form of (5)

min
$$tf_0(x) + \phi(x)$$

s.t. $Ax = b$. (6)

Let $x^*(t)$ be optimal solution of (6). From KKT conditions, $\exists \ \hat{\nu} \in \mathbb{R}^p$ such that

$$Ax^{*}(t) = b, \ f_{i}(x^{*}(t)) < 0,$$

$$\nabla f_{0}(x^{*}(t)) + \sum_{i=1}^{m} \frac{1}{-tf_{i}(x^{*}(t))} \nabla f_{i}(x^{*}(t)) + A^{T}(\hat{\nu}/t) = 0.$$
(7)

The set $\{x^*(t) : t > 0\}$ is the called the *central path* associated to (1).

・ 同 ト ・ ヨ ト ・ ヨ ト

"Minimal" preliminaries on Lagrangian dual function

Consider following function, called Lagrangian associated to (1):

$$L(x,\lambda,\nu) = f_0(x) + \sum_{i=1}^m \lambda_i f_i(x) + \nu^T A x, \text{ for some } \lambda \ge 0, \nu.$$
(8)

- As $\lambda \ge 0$, $L(x, \lambda, \nu) \le f(x) \forall$ feasible $x \in \text{dom}(f)$.
- Hence $g(\lambda, \nu) := \inf_{x \in \text{dom}(f)} L(x, \lambda, \nu) \le p^*$.
- In other words, for any $\lambda \ge 0$, $g(\lambda, \nu)$ is a lower bound on p^* .
- In particular, if (1) is convex and $\bar{x} \in \text{dom} f$, $\bar{\lambda} \ge 0$, and $\bar{\nu}$ satisfy

$$\nabla f_0(\bar{x}) + \sum_{i=1}^m \bar{\lambda}_i \nabla f_i(\bar{x}) + A^T \bar{\nu} = 0, \qquad (9)$$

then $L(\bar{x}, \bar{\lambda}, \bar{\nu}) = \inf_{x \in \text{dom}(f)} L(\bar{x}, \bar{\lambda}, \bar{\nu}) = g(\bar{\lambda}, \bar{\nu})$ is a lower bound on p^* .

◆□▶ ◆□▶ ◆∃▶ ◆∃▶ = のQ@

From (7), we can observe that $x^*(t)$, $\lambda_i^*(t) = -\frac{1}{tf_i(x^*(t))} > 0$, i = 1, ..., m, and $\nu^*(t) = \hat{\nu}/t$ satisfy (9). Hence the following is a lower bound on p^* :

$$L(x^{*}(t), \lambda^{*}(t), \nu^{*}(t)) = f_{0}(x^{*}(t)) + \sum_{i=1}^{m} \lambda^{*}_{i}(t) f_{i}(x^{*}(t)) + \nu^{*}(t)^{T} (Ax^{*}(t) - b)$$

= $f_{0}(x^{*}(t)) - m/t$
 $\leq p^{*}$

Thus, $f_0(x^*(t)) - p^* \le m/t$; as t grows $x^*(t)$ gets closer to x^* as predicted.

Logarithmic barrier(*cont'd*)

Interpretation of central path via KKT conditions

From (7), $x = x^*(t)$ from central path 'almost' satisfies the KKT conditions:

$$\begin{aligned} Ax &= b, \ f_i(x) \leq 0, \\ \lambda \geq 0, \\ \nabla f_0(x) + \sum_{i=1}^m \lambda_i \nabla f_i(x) + A^T \nu = 0, \\ -\lambda_i f_i(x) = 1/t, \ i = 1, \dots, m. \end{aligned}$$

3

Algorithm (**Barrier method**)

given interior solution x, $t := t^{(0)}$, $\mu > 1$, tolerance $\epsilon > 0$.

repeat

- 1. Centering step: Starting at x, compute $x^*(t)$ by solving (6).
- 2. Update $x := x^*(t)$.
- 3. Quit if $m/t < \epsilon$.
- 4. Increase t: $t := \mu t$.
- First proposed by Fiacco and McCormick in the 1960s, in name of SUMT.
- We assume to use Newton's method for Centering step.

Newton step for centering from Newton step for modified KKT

The Newton step Δx_{nt} for (6) is given by

$$\begin{bmatrix} t\nabla^2 f_0(x) + \nabla^2 \phi(x) & A^T \\ A & 0 \end{bmatrix} \begin{bmatrix} \Delta x_{\mathsf{nt}} \\ \nu_{\mathsf{nt}} \end{bmatrix} = -\begin{bmatrix} t\nabla f_0(x) + \nabla \phi(x) \\ 0 \end{bmatrix}.$$
(10)

We will derive Δx_{nt} of (10) from the Newton step for the modified KKT conditions:

$$Ax = b,$$

$$\nabla f_0(x) + \sum_{i=1}^m \lambda_i \nabla f_i(x) + A^T \nu = 0,$$

$$-\lambda_i f_i(x) = 1/t, \ i = 1, \dots, m.$$
(11)

In doing so, we first eliminate $\lambda_i = -rac{1}{t f_i(\mathbf{x})}$ to get

$$Ax = b \nabla f_0(x) + \sum_{i=1}^m \frac{1}{-tf_i(x)} \nabla f_i(x) + A^T \nu = 0.$$
 (12)

・ 同 ト ・ ヨ ト ・ ヨ ト …

Newton step for centering from Newton step for modified KKT(cont'd)

To find the Newton step for solving (12), we consider its Taylor approximation, by

$$\nabla f_{0}(x+\nu) + \sum_{i=1}^{m} \frac{1}{-tf_{i}(x+\nu)} \nabla f_{i}(x+\nu)$$

$$\approx \nabla f_{0}(x) + \sum_{i=1}^{m} \frac{1}{-tf_{i}(x)} \nabla f_{i}(x) + \nabla^{2} f_{0}(x)\nu$$
(13)

$$+ \sum_{i=1}^{m} \frac{1}{-tf_i(x)} \nabla^2 f_i(x) v + \sum_{i=1}^{m} \frac{1}{tf_i(x)^2} \nabla f_i(x) \nabla f_i(x)^T v.$$

Using this approximation in place of nonlinear terms, we get

$$Hv + A^{T} \nu = -g, \ Av = 0, \tag{14}$$

where,

$$\begin{aligned} H &= \nabla^2 f_0(x) + \sum_{i=1}^m \frac{1}{-tf_i(x)} \nabla^2 f_i(x) + \sum_{i=1}^m \frac{1}{tf_i(x)^2} \nabla f_i(x) \nabla f_i(x)^T \\ g &= \nabla f_0(x) + \sum_{i=1}^m \frac{1}{-tf_i(x)} \nabla f_i(x). \end{aligned}$$

イロト 不得 トイヨト イヨト 二日

Newton step for centering from Newton step for modified KKT(cont'd)

But,

$$H=
abla^2f_0(x)+(1/t)
abla^2\phi(x),\;g=
abla f_0(x)+(1/t)
abla \phi(x).$$

Hence Δx_{nt} and ν_{nt} of (10) satisfy

$$tH\Delta x_{nt} + A^T \nu_{nt} = -tg, \ A\nu_{nt} = 0.$$

Comparing this with (14), we get

$$v = \Delta x_{nt}, \ \nu = (1/t)\nu_{nt}.$$

Hence the Newton's direction for centering step is the same as the Newton's direction for solving the modified KKT conditions.
