## • Comments on Rate-Dependent Behavior of Soils

- Assumptions on the theory of consolidation and their possible solutions

i)  $k_{v}$  (or  $k_{h}$ ) remains constant during consolidation.

Figure 25.15 Changes in permeability and compressibility during an increment of consolidation pressure.

Compression loading, decrease *e* and thus decrease k.

 $e \propto \log k (C_k (= \Delta e / \Delta \log k) = \text{constant})$ 

 $\Rightarrow$  if e-log  $\sigma_{v}$  relationship and C<sub>k</sub> are given, variation of k during consolidation can be

considered. 
$$(c_v = \frac{k}{\gamma_w m_v})$$

SNU Geotechnical and Geoenvironmental Engineering Lab.

ii)  $a_v$  or  $m_v$  remains constant during consolidation.

For virgin compression range,  $a_v$  (or  $m_v$ ) decreases with increasing  $\sigma'_v$ .  $\Rightarrow$  If  $m_v = f(\sigma'_v)$  is given, non-linear compressibility

can be considered.

Figure 16.1 Relation between end-of-primary void ratio and effective vertical pressure for natural clays from Mexico City, Louiseville, and San Francisco (top to bottom). Effective vertical pressure plotted (a) to natural scale and (b) to logarithmic scale.

- No drained creep effect throughout the primary consolidation process.

In terms of void ratio, the rate of compression of a sublayer is expressed by

$$\frac{de}{dt} = \left(\frac{\partial e}{\partial \sigma_{v}}\right) \frac{d\sigma_{v}}{dt} + \left(\frac{\partial e}{\partial t}\right)_{\sigma_{v}} = a_{vs} \frac{d\sigma_{v}}{dt} + a_{vt} \quad \dots \quad (1)$$

$$\int_{0}^{t} de = \int_{0}^{t_{p}} \left(a_{vs} \frac{d\sigma_{v}}{dt} + a_{vt}\right)^{0} dt + \int_{t_{p}}^{t} a_{vt} dt$$

$$= a_{vs} \frac{d\sigma_{v}}{dt} + a_{vt} = a_{vt} + a_{vt} = a_{vt} + a_{vt} = a_{vt} + a_{vt} + a_{vt} = a_{vt} + a_{vt} = a_{vt} + a_{vt} + a_{vt} + a_{vt} = a_{vt} + a_{vt} + a_{vt} = a_{vt} + a_{vt} + a_{vt} + a_{vt} = a_{vt} + a_{vt} + a_{vt} + a_{vt} + a_{vt} + a_{vt} = a_{vt} + a_{vt$$

SNU Geotechnical and Geoenvironmental Engineering Lab.

• Comments on secondary compression settlements

$$S = \frac{C_{\alpha}}{1 + e_0} H \log \frac{t}{t_p}$$

- 1.  $C_{\alpha}$  is assumed to be constant with time.
- 2.  $c_{\alpha}/c_{c}^{*}$  is constant in both the compression and recompression ranges.

Material	$C_{lpha} / C_c^*$
Granular soils including rockfill	$0.02\pm0.01$
Shale and mudstone	$0.03\pm0.01$
Inorganic clays and silts	$0.04\pm0.01$
Organic clays and silts	$0.05\pm0.01$
Peat and muskeg	$0.06\pm0.01$

Table 16.1 Values of  $C_{\alpha}/C_{c}^{*}$  for Geotechnical Materials

## Advanced Soil Mechanics I

- 3.  $c_{\alpha}$  is assumed to be not influenced by thickness of clay layer and magnitude of stress increment and to be a function of applied stress level and soil type.
- 4.  $t_p$  for compression range >  $t_p$  for recompression range.
  - $C_{\alpha}$  for compression range >  $C_{\alpha}$  for recompression range.

 $\rightarrow$  Preloading provides significant effect on reducing secondary compression settlement and controlling consolidation behavior by decreasing both  $C_{\alpha}$  and  $t_{p}$  values after treatment, in addition to reduce primary consolidation settlement.

## • Influence of stress increment range, based on stress history.

$$\frac{d\sigma'_{v}}{dt} = -\frac{du}{dt}$$
 From eq. (1) in page 2-146  
$$-\frac{du}{dt} = \frac{\frac{de}{dt} - a_{vt}}{a_{vs}}$$

Increase in either  $a_{vs}$  or  $a_{vt}$  slows dissipation.

In recompression range,  $a_{vs}$  is low.  $\rightarrow$  dissipation rate is fast. In compression range,  $a_{vs}$  is high.  $\rightarrow$  dissipation rate is slow.

## • Excess porewater pressure behavior for a pressure increment spanning the preconsolidation pressure

 $\rightarrow$  Test conditions

- Free drain to the top, impermeable at the bottom.
- Four piezometer at the quarter points in depth.
- Apply the pressure increments form 28 to 55 kPa (recompression range) and from

110 to 152 kPa (spanning preconsolidation pressure).

Determine pore pressure of various points from top to bottom with time.

→ The pressure increment from 28 to 55 kPa and initial part of the pressure increment from 110 to 152 kPa ; small  $a_{vs} \Rightarrow$  pore pressure dissipate rapidly.

 $\rightarrow$  But approaching  $\sigma_p^{\cdot}$  for  $\Delta \sigma_v^{\cdot}$  from 110 to 152 kPa,  $a_{vs}$  abruptly increases and there is a dramatic reduction in the rate of pore pressure dissipation (No significant effect of reduction in permeability which is always gradual.)

**Figure 16.15** (a) Relation between e and log  $\sigma_v$  and (b) Corresponding relation between e and log  $k_v$  for the pressure increments in Figs. 16.13 and 16.14.

Figure 16.14 Excess porewater pressure behavior for a pressure increment spanning the preconsolidation pressure.
