Homework #2 - SOLUTIONS

Due: Apr 19, 23:59

Construct a program using Excel spreadsheet, python, or any computer software to predict the substrate and biomass concentration (S and X_a) at time t for a batch-type bioreactor by numerical approach.

Use the following initial conditions and growth parameters:

 $S^0 = 500 \ mg \ COD/L$ $X^0_a = 100 \ mg \ VSS/L$ $\hat{q} = 20 \ g \ VSS/g \ COD-d$ K=100 mg COD/L Y=0.4 g VSS/g COD b=0.1/d

1) What are the substrate and biomass concentrations at t = 0.1 dcalculated by setting the following values as Δt ?

i.
$$\Delta t = 0.0001 d$$
; ii. $\Delta t = 0.001 d$; iii. $\Delta t = 0.05 d$

2) Compare the results for the numerical solution with different Δt values. Which one do you think will be the most accurate? Why? For $\Delta t = 0.05 d$, obtain the solutions for substrate and biomass concentrations at t = 0.5 d. What do you get? How would you describe the reason for getting that result?

Submit the Excel spreadsheet (or computer language code + figures) you have constructed. Also do not forget to provide written descriptions that answer the questions above. You can use any format for these descriptions (e.g., writing on the spreadsheet, figure, separate paper, etc.) Grading will be given based on the correctness of your employment of the numerical approach, the correctness of your numerical solution, and the reasonableness of your written answers.

(100 points)

Solution)

Following is an example spreadsheet (the structure and the extent of embedded calculations are up to the decision of each student)

Imput parameters Time (d) S X_a 2 S^0 500 mg COD/L 0.000 500 100 3 X_a^0 100 mg VSS/L 0.001 498.3 100.7 4 q 20 g VSS/g COD-d 0.002 496.7 101.3 5 K 100 mg COD/L 0.003 495.0 102.0 6 Y 0.4 g VSS/g COD 0.004 493.3 102.7 7 b 0.1 1/d 0.005 491.6 103.3 8 Δt 0.001 d 0.007 489.8 104.7

36 0.034 437.5 124.6	5

Results for 0.1 d:

 $\Delta t = 0.0001 \ d$: $S = 278.7 \ mg \ COD/L, \ X_a = 187.1 \ mg \ VSS/L$ $\Delta t = 0.001 \ d$: $S = 279.3 \ mg \ COD/L, \ X_a = 186.9 \ mg \ VSS/L$ $\Delta t = 0.05 \ d$: $S = 309.5 \ mg \ COD/L, \ X_a = 175.0 \ mg \ VSS/L$

Results for 0.5 d using Δt = 0.05 d: S = -26.8 mg COD/L, X_a = 299.0 mg VSS/L (negative S value indicates that the numerical approximation failed)

The smaller the Δt , the higher the accuracy of numerical approximation. This is due to the nature of numerical approximation – the derivatives ($\Delta t \rightarrow 0$) are replaced with algebraic calculations (nonzero Δt). Therefore as Δt gets longer the calculation error will get larger. If Δt exceeds a certain value for an explicit method, the calculation error will be magnified with the progress of calculation such that we may get a stable solution as we see from Δt =0.05 d in this case.
