## Lecture Note \#3 (Spring, 2022)

## Electrochemical kinetics

1. Potential on reaction rate
2. Butler-Volmer equation
3. Exchange current
4. Charge transfer resistance
5. Tafel plot

Fuller \& Harb (textbook), ch.3, Bard (ref.), ch.3, Oh (ref.), ch. 4

## Current: expression of reaction rate

- Current ( $i$ ) : the rate of the electrode reactions
- Charge $(q) \rightarrow$ extent of chemical change at each electrode. The charge required to convert N mol of starting material to product in an $n e^{-}$ electrode reaction is calculated using Faraday's law of electrolysis

$$
q=\int i d t=n N F=n m F / M \quad \text { for time } t
$$

where $F$ : Faraday constant $\left(96,485 \mathrm{C} \mathrm{mol}^{-1}\right)$

$$
\begin{aligned}
i(\text { amperes })= & \frac{d Q}{d t}(\text { coulombs } / \mathrm{s}) \\
\frac{Q}{n F} \frac{(\text { coulombs })}{(\text { coulombs } / \mathrm{mol})} & =N(\text { mol electrolyzed }) \\
\text { Rate }(\mathrm{mol} / \mathrm{s}) & =\frac{d N}{d t}=\frac{i}{n F}
\end{aligned}
$$

## I-V relation

Plot of cell currents versus the cell voltages (volt + am(pere) + mogram)

Not linear $\rightarrow$ electrochemical cells do not obey Ohm's law
Overpotential (or overvoltage, polarization) $\eta=E-E_{\text {eq }}$

$$
E_{e q}=E^{0}
$$

## I-V curve : Butler-Volmer equation

## Nernst equation : equilibrium expression

$\rightarrow$ electrode reaction rate? (kinetics)
$\rightarrow$ relationship between potential and rate of electrode reaction (which determine current) : I-V curve

## I-V relation: Butler-Volmer equation, Tafel equation

One-step, one-electron kinetic relationships (Butler-Volmer approach):

$E-E^{0}=\eta$ : overpotential
Control the magnitude of the current by changing the potential (and vise versa). Potential and current cannot be adjusted at the same time.

## Electron transfer at an electrode

Reduction \& oxidation at electrode are accomplished by heterogeneous electron transfer reactions since electron transfer occurs at the interface between electrode and solution $\rightarrow$ relationship between potential and rate of electrode reaction (which determine current)
$\rightarrow$ Butler-Volmer equation

FIGURE 19-10 Steps in the reaction $\mathrm{Ox}+n e \rightleftharpoons$ Red at an electrode. Note that the surface layer is only a few molecules thick. (Adapted from: A. J. Bard and L. R. Faulkner, Electrochemical Methods, p. 21, Wiley: New York, 1980. Reprinted by permission of John Wiley \& Sons, Inc.)

## Dynamic equilibrium

$$
\mathrm{O}+\mathrm{e} \underset{k_{b}}{\stackrel{k_{f}}{=} R} \text { or } A+e=B
$$

Rate of the forward process

$$
v_{f}(\mathrm{M} / \mathrm{s})=\mathrm{k}_{\mathrm{f}} \mathrm{C}_{\mathrm{A}}
$$

Rate of the reverse reaction

$$
v_{b}=k_{b} C_{B}
$$

Rate const, $\mathrm{k}_{\mathrm{f}}, \mathrm{k}_{\mathrm{b}}$ : $\mathrm{s}^{-1}$ Net conversion rate of A \& B

$$
v_{\text {net }}=k_{f} C_{A}-k_{b} C_{B}
$$

At equilibrium, $\mathrm{v}_{\text {net }}=0$

$$
\mathrm{k}_{\mathrm{f}} / \mathrm{k}_{\mathrm{b}}=\mathrm{K}=\mathrm{C}_{\mathrm{B}} / \mathrm{C}_{\mathrm{A}}
$$

*kinetic theory predicts a constant concentration ratio at equilibrium, just as thermodynamics
At equilibrium, kinetic equations $\rightarrow$ thermodynamic ones
$\rightarrow$ dynamic equilibrium (equilibrium: nonzero rates of $k_{f} \& k_{b}$, but equal)
Exchange velocity

$$
\mathrm{v}_{0}=\mathrm{k}_{\mathrm{f}}\left(\mathrm{C}_{\mathrm{A}}\right)_{\mathrm{eq}}=\mathrm{k}_{\mathrm{b}}\left(\mathrm{C}_{\mathrm{B}}\right)_{\mathrm{eq}}
$$

## Relationship between current and heterogeneous rate constants

Faraday's law: chemical reaction $\rightarrow$ electric current $\rightarrow$ an indicator of reaction rate
Amount of electricity,

$$
q=n F N
$$

n : electron number, N : number of moles, F : Faraday constant $(96,485$ C/mol)
e.g., $\mathrm{PbSO}_{4}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{I}) \rightarrow 2 \mathrm{e}^{-}+\mathrm{PbO}_{2}(\mathrm{~s})+\mathrm{HSO}_{4}^{-}(\mathrm{aq})+3 \mathrm{H}^{+}(\mathrm{aq})$

$$
\mathrm{q} / 2 \mathrm{~F}=-\Delta \mathrm{N}_{\mathrm{PbSO} 4}=-\Delta \mathrm{N}_{\mathrm{H} 2 \mathrm{O}} / 2=\Delta \mathrm{N}_{\mathrm{PbO} 2}=\Delta \mathrm{N}_{\mathrm{HSO} 4-}=\Delta \mathrm{N}_{\mathrm{H}+} / 3
$$

The passage of two moles of electrons = destroy one mole of $\mathrm{PbSO}_{4}$, destroy two moles of water, create one mole of $\mathrm{PbO}_{2} \ldots$

If we generalize this result and apply it to the oxidation reaction,

$$
R \rightarrow n e^{-}+O
$$

Then,

$$
\mathrm{q} / \mathrm{nF}=-\Delta \mathrm{N}_{\mathrm{R}}=\Delta \mathrm{N}_{\mathrm{O}}
$$

$\mathrm{I}=\mathrm{dq} / \mathrm{dt}=\mathrm{nFdN} / \mathrm{dt}$

$$
\begin{gathered}
\mathrm{I} / \mathrm{nF}=-\mathrm{dN}_{\mathrm{R}} / \mathrm{dt}=\mathrm{dN} / \mathrm{dt}=\text { rate } \\
\mathrm{O}+\mathrm{e}^{-}=\mathrm{R} \\
\mathrm{E}_{\mathrm{n}}=\mathrm{E}^{0}-\mathrm{RT} / \mathrm{F} \ln \left(\mathrm{c}_{\mathrm{R}} / \mathrm{c}_{\mathrm{O}}\right)
\end{gathered}
$$

depends on the concentrations of the two species and $\mathrm{E}^{0^{\prime}}$
"=" means,

$$
\begin{aligned}
& \mathrm{R} \rightarrow \mathrm{e}^{-}+\mathrm{O} \\
& \mathrm{O}+\mathrm{e}^{-} \rightarrow \mathrm{R}
\end{aligned}
$$

At $E_{n}\left(E_{\text {eq }}\right)$, the rates

$$
r_{o x}\left(E_{n}\right)=r_{r d}\left(E_{n}\right)
$$

because no net reaction occurs. The rate $r$ depend on the electrode potential E .

What exactly is meant by the "rate" of an electrode reaction?
At the potential of E ,

$$
r_{\text {net }}(E)=r_{o x}(E)-r_{r d}(E)
$$

net reaction rate: the rate at which $R$ is destroyed, or the rate at which $O$ is created, per unit area of electrode (unit of $\mathrm{mol} \cdot \mathrm{m}^{-2} \mathrm{~s}^{-1}$ ) "heterogeneous reaction rate"

$$
\begin{gathered}
r_{\text {net }}(E)=-(1 / A)\left(d N_{R} / d t\right)=(1 / A)\left(d N_{O} / d t\right) \\
\mathbf{r}_{\mathbf{o x}}(E)=\mathbf{k}_{\mathbf{o x}}(E) \mathbf{c}_{\mathbf{R}}^{\mathbf{s}}
\end{gathered}
$$

"s" means that the concentrations at the electrode surface
$\mathrm{k}_{\mathrm{ox}}(\mathrm{E})$ : oxidative rate constant $\left(\mathrm{ms}^{-1}\right)$

$$
r_{r d}(E)=k_{r d}(E) c_{o}^{s}
$$

$\mathrm{k}_{\mathrm{rd}}(\mathrm{E})$ : reductive rate constant

$$
r_{\text {net }}(\mathrm{E})=\mathrm{l} / \mathrm{nAF}=\mathrm{i} / \mathrm{nF}
$$

From $r_{\text {net }}(E)=r_{o x}(E)-r_{r d}(E), r_{o x}(E)=k_{o x}(E) c_{R}, r_{r d}(E)=k_{r d}(E) c_{o}$

Relate the faradaic current and rate constants

$$
\mathrm{i}=\mathrm{nF}\left[\mathrm{k}_{\mathrm{ox}} \mathrm{c}_{\mathrm{R}}{ }^{\mathrm{s}}-\mathrm{k}_{\mathrm{rd}} \mathrm{c}_{\mathrm{o}} \mathrm{~s}\right]
$$

cf) $k_{o x}=k_{a}$ of anode, $k_{r d}=k_{c}$ of cathode
when $\mathrm{k}_{\mathrm{ox}}(\mathrm{E}) \mathrm{c}_{\mathrm{R}}{ }^{s}=\mathrm{k}_{\mathrm{rd}}(\mathrm{E}) \mathrm{c}_{\mathrm{O}}{ }^{\mathrm{s}} \rightarrow$ zero current $\rightarrow$ equilibrium when $\mathrm{k}_{\mathrm{ox}}(\mathrm{E}) \mathrm{c}_{\mathrm{R}}{ }^{\mathrm{s}}>\mathrm{k}_{\mathrm{rd}}(\mathrm{E}) \mathrm{c}_{\mathrm{O}}{ }^{\mathrm{s}} \rightarrow$ anodic current $\left(\mathrm{i}_{\mathrm{a}}\right) \rightarrow$ oxidation of R to O when $\mathrm{k}_{\mathrm{ox}}(\mathrm{E}) \mathrm{c}_{\mathrm{R}}{ }^{\mathrm{s}}<\mathrm{k}_{\mathrm{rd}}(\mathrm{E}) \mathrm{c}_{\mathrm{O}}{ }^{\mathrm{s}} \rightarrow$ cathodic current $\left(\mathrm{i}_{\mathrm{c}}\right) \rightarrow$ reduction of O to R

Figure 3.3 The relationship between potential, electron energy, and the direction of a faradaic reaction.

Oh, ch.4, Fig. 4-3

## Potential dependence of heterogeneous rate constants

$$
\mathrm{O}+\mathrm{ne}^{-}=\mathrm{R}
$$

Transition state model,

$$
\mathrm{k}_{\mathrm{rd}}=\mathrm{k}_{\mathrm{f}}=\operatorname{Aexp}\left(-\Delta \mathrm{G}_{\mathrm{f}}^{\ddagger} / \mathrm{RT}\right)
$$

where $\Delta G_{f}^{\ddagger}$ is the free energy of activation and $A$ is a frequency factor which accounts for the rate of collision of the electroactive molecule with the electrode surface
cf) $k_{o x}=k_{b}$ of anode, $k_{r d}=k_{f}$ since forward direction $(\rightarrow)$ is reduction one.

(a) equilibrium between O and R
$\mathrm{O} \rightarrow \mathrm{R}$ : pass over the activation free energy barrier, $\Delta \mathrm{G}_{\mathrm{f}}^{\ddagger}$
$R \rightarrow O$ : pass over the activation free energy barrier, $\Delta G_{b} \ddagger$
At equilibrium, $\Delta \mathrm{G}_{\mathrm{f}}^{\ddagger}=\Delta \mathrm{G}_{\mathrm{b}}^{\ddagger} \rightarrow$ probability of electron transfer is the same in each direction $\rightarrow$ no net curent $\rightarrow i_{c}+i_{a}=0$ No net current means same rates between forward and backward (not zero current) $\rightarrow$ exchange current $i_{0}$ at equilibrium; $i_{0}=i_{c}=-i_{a}$

$$
\mathrm{i}_{0} \uparrow \text { as } \Delta \mathrm{G} \downarrow
$$

(b) net reduction
applying negative potentials reduction: more negative potential $\rightarrow \mathrm{k}_{\mathrm{f}}\left(\right.$ or $\left.\mathrm{k}_{\mathrm{rd}}\right) \uparrow, \mathrm{k}_{\mathrm{b}} \downarrow$

Negative potential $\mathrm{E} \rightarrow$ lower $\Delta \mathrm{G}_{\ddagger} \ddagger$ and raise $\Delta \mathrm{G}_{\mathrm{b}} \ddagger$
Potential change $\mathrm{E}-\mathrm{E}^{0} \rightarrow$ free energy change $-\mathrm{nF}\left(\mathrm{E}-\mathrm{E}^{0}\right) \Rightarrow$ part of this energy change (factor $\alpha$ ) $\rightarrow$ decrease in the activation barrier for reduction (forward reaction) ; part (factor ( $1-\alpha$ )) $\rightarrow$ increase in the activation barrier for oxidation
$\Delta \mathrm{G}_{\mathrm{f}}^{\ddagger}=\Delta \mathrm{G}^{0 \ddagger}-\alpha \mathrm{nF}\left(\mathrm{E}-\mathrm{E}^{0^{\prime}}\right)$
$\Delta G_{b}{ }^{\ddagger}=\Delta G^{0 \ddagger}+(1-\alpha) n F\left(E-E^{0}\right)$
Applying potential to the electrode $\rightarrow$ activation free energy barrier $\alpha$; "transfer coefficient" or "symmetry factor" since $\alpha$ is a measure of the symmetry of the energy barrier $\rightarrow$ a symmetrical energy barrier ( $\alpha=0.5$ ), real systems: $0.3 \sim 0.7$ semiconductor: $\sim 0$ or $\sim 1$

Actually,

$$
\mathrm{O}+\alpha \mathrm{ne}^{-} \rightarrow \mathrm{R}-(1-\alpha) \mathrm{ne}^{-}
$$

$\alpha,-(1-\alpha)$; orders of the reductive and oxidative processes
another interpretation of $\alpha$ : increasing electrochemical activity of electrons $\rightarrow$ it accelerates the reductive process and retards the oxidative process $\rightarrow$ $\alpha$ is the fraction of the increase $r_{r d},(1-\alpha)$ is the fraction that diminishes $r_{o x}$ $\alpha=0.5$; perfect symmetric, these fractions are equal

Fig. 4.4 Energy profiles for the cases (a) $\alpha_{\mathrm{c}} \approx 0$; (b) $\alpha_{\mathrm{c}} \approx \frac{1}{2}$; (c) $\alpha_{\mathrm{c}} \approx 1$.
Arrhenius form,

$$
\begin{aligned}
& k_{f}=k^{0} \exp \left[-\alpha n F\left(E-E^{0}\right) / R T\right] \\
& k_{b}=k^{0} \exp \left[(1-\alpha) n F\left(E-E^{0}\right) / R T\right]
\end{aligned}
$$

Where $k^{0}$ is the standard rate constant, $k_{f}=k_{b}=k^{0}$ at $E^{0} . k^{0}, \alpha \rightarrow$ rate constant. Relationship between potential and rate

## Relationship between current and potential

$$
\begin{aligned}
& \mathrm{i}_{\mathrm{c}}=\mathrm{nFc}_{O}{ }^{\mathrm{s}} \mathrm{k}_{\mathrm{f}} \text { and } \mathrm{i}_{\mathrm{a}}=-\mathrm{nF} \mathrm{c}_{\mathrm{R}}{ }^{\mathrm{s} k_{\mathrm{b}}} \\
& \mathrm{i}_{\mathrm{c}}=\mathrm{nFk}^{0} \mathrm{c}_{\mathrm{o}}{ }^{\mathrm{s}} \exp \left\{-\alpha \mathrm{nF}\left(\mathrm{E}^{-E^{0}}\right) / R T\right\} \\
& \mathrm{i}_{\mathrm{a}}=-\mathrm{nFk} \mathrm{c}_{\mathrm{R}}{ }^{\mathrm{s}} \exp \left\{(1-\alpha) \mathrm{nF}\left(E-E^{0}\right) / R T\right\} \\
& i=i_{c}+i_{a}
\end{aligned}
$$

Butler-Volmer equation

$$
\mathrm{i}=\mathrm{nFk} k^{0}\left[\mathrm{c}_{0}{ }^{\mathrm{s}} \exp \left\{-\alpha \mathrm{nF}\left(\mathrm{E}-\mathrm{E}^{0}\right) / R T\right\}-\mathrm{c}_{\mathrm{R}}{ }^{\mathrm{s}} \exp \left\{(1-\alpha) \mathrm{nF}\left(\mathrm{E}-\mathrm{E}^{0}\right) / R T\right\}\right]
$$

This relationship links the faradaic current, electrode potential, the concentrations of electroactive species at the electrode surface

$i$ and $i_{c}$ and $i_{a}$ as a function of potential $E$; negative $E \uparrow \rightarrow i_{c} \uparrow$ (forward reaction), positive $E \uparrow \rightarrow i_{a} \uparrow$ (backward)
$\mathrm{k}^{0} ; 1 \sim 50 \mathrm{~cm} \cdot \mathrm{~s}^{-1}$ for very fast reactions, $10^{-9} \mathrm{~cm} \cdot \mathrm{~s}^{-1}$ for very slow reactions.
Exchange current density $\mathrm{i}_{0} ; 10 \mathrm{~A} \cdot \mathrm{~cm}^{-2} \sim 1 \mathrm{pA} \cdot \mathrm{cm}^{-2}$

## I-V: Electroless deposition

## ■ Electrochemical Point of View: Mixed Potential Theory (혼성전위)

- Mixed potential theory: overlap of two independent electrochemical reaction

Metal ion reduction

$$
\begin{aligned}
& \mathrm{M}^{n+}+\mathrm{ne}^{-} \rightarrow \mathrm{M} \\
& i_{c}=f(E)
\end{aligned}
$$

Reducing agent oxidation

$$
\begin{aligned}
& \text { Red } \rightarrow \mathrm{Ox}^{\mathrm{m}+}+\mathrm{me}^{-} \\
& i_{a}=f(E)
\end{aligned}
$$

- The potential where the total current becomes 0 is the mixed potential.

$$
i_{\text {total }}=i_{c}+i_{a}
$$

Electrochemistry as closed loop: $i_{a}=i_{c}$

$$
i_{\mathrm{c}}=\left|i_{\mathrm{a}}\right|=i \text { (electrolyte) }
$$

The effect of the value of $\mathrm{k}_{0}$ on the current density close to $\mathrm{E}_{\text {eq }}$ (a) $\mathrm{k}_{0}$ large (b) $\mathrm{k}_{0}$ smaller

At equilibrium, zero net current, $i_{c}=-i_{a}$
Butler-Volmer equation (kinetics) $\rightarrow$ Nernst equation (thermodynamics)

$$
E=E^{0}-(R T / n F) \ln \left(c_{R}{ }^{s} / c_{o}{ }^{s}\right)
$$

$\mathrm{i}_{0}=\mathrm{i}_{\mathrm{c}}=\mathrm{nFk} \mathrm{c}^{0} \mathrm{c}_{0}{ }^{\mathrm{s}} \exp \left\{-\alpha \mathrm{nF}\left(\mathrm{E}-\mathrm{E}^{0}\right) / R T\right\}=\mathrm{i}_{\mathrm{a}}=-\mathrm{nFk}{ }^{0} \mathrm{c}_{\mathrm{R}}{ }^{\mathrm{s}} \exp \left\{(1-\alpha) \mathrm{nF}\left(\mathrm{E}-\mathrm{E}^{0}\right) / R T\right\}$
$\Rightarrow$

$$
\mathrm{i}_{0}=\mathrm{nFk}^{0}\left(\mathrm{c}_{O^{s}}\right)^{1-\alpha}\left(\mathrm{c}_{\mathrm{R}}{ }^{\mathrm{s}}\right)^{\alpha}
$$

high exchange current density $\rightarrow$ high reaction rate

$\mathrm{i}_{0}$ : 교환전류
(exchange current)

교환전류 ( $\mathrm{i}_{0}$ )

## Plot I-V relation

 using Butler-Volmer equation if charge-transfer is rate-
determining step:

어떤 전기화학 반응 $(\mathrm{O}+e=\mathrm{R})$ 에서 전하 전달이 전체 속도를 결정한다고 가정하 고, 다음의 조건이 주어졌을 때 버틀러-볼머 식을 이용하여 전압과 전류의 관계
를 그리시오; $\mathrm{A}=0.1 \mathrm{~cm}^{2}, E^{0}=-0.15 \mathrm{~V}(v s . \mathrm{SCE}), k^{0}=10^{-4} \mathrm{~cm} / \mathrm{sec}, T=298$
$\mathrm{~K}, \alpha=0.5, C_{\mathrm{O}}{ }^{*}=5.0 \mathrm{mM}, C_{\mathrm{R}}{ }^{*}=1.0 \mathrm{mM}$

풀이 버틀러-볼머 식을 이용하여 전압에 따른 전류를 모사하기 위해서 먼저 평형 전압 $\left(E_{\mathrm{eq}}\right)$ 과 교환 전류 $\left(i_{0}\right)$ 를 알아야 한다. 평형 전압 $\left(\mathrm{E}_{\mathrm{eq}}\right)$ 을 계산하면 다음과 같다.

$$
\begin{aligned}
E_{\text {eq }} & =E^{0^{\prime}}+\frac{R T}{F} \ln \frac{C_{0}^{*}}{C_{\mathrm{R}}^{*}} \\
& =(-0.15 \mathrm{~V})+\frac{(8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})(298 \mathrm{~K})}{\left(9.65 \times 10^{4} \mathrm{C} / \text { equiv. }\right)} \ln \frac{\left(5 \times 10^{-3} \mathrm{M}\right)}{\left(10^{-3} \mathrm{M}\right)}=-0.11 \mathrm{~V}
\end{aligned}
$$

주어진 조건에서 $i_{0}$ 는 다음과 같이 계산된다.

$$
\begin{aligned}
i_{0}= & F A k^{0} C_{\mathrm{O}}^{(1-\alpha)} C_{\mathrm{R}}^{*} \\
= & \left(9.65 \times 10^{4} \mathrm{Coul} / \text { equiv }\right) \times\left(0.1 \mathrm{~cm}^{2}\right) \times\left(10^{-4} \mathrm{~cm} / \mathrm{sec}\right) \\
& \times\left(5 \times 10^{-6} \mathrm{~mol} / \mathrm{cm}^{3}\right)^{0.5} \times\left(1 \times 10^{-6} \mathrm{~mol} / \mathrm{cm}^{3}\right)^{0.5} \\
= & 2.2 \mu \mathrm{~A}
\end{aligned}
$$

위 계산에서 각 변수를 $\operatorname{cgs}$ 단위로 표현하고 농도의 단위를 반드시 $\mathrm{mol} / \mathrm{cm}^{3}$ 로 사용하여야 전류가 암페어(amperes)의 단위를 갖게 된다.

$$
\left(\frac{\text { Coul }}{\text { equiv. }}\right)\left(\mathrm{cm}^{2}\right)\left(\frac{\mathrm{cm}}{\mathrm{sec}}\right)\left(\frac{\mathrm{mol}}{\mathrm{~cm}^{3}}\right)^{0.5}\left(\frac{\mathrm{~mol}}{\mathrm{~cm}^{3}}\right)^{0.5}=\frac{\text { Coul }}{\mathrm{sec}}=\text { Amperes }
$$

Oh, ch. 4
$i_{a}, i_{c}, i_{\text {net }}, \eta_{c}, \eta_{a}, E_{\text {eq }}$

The effect of exchange current density on overpotential 교환전류 ( $\mathrm{i}_{0}$ )

Butler-Volmer equation/io
$\mathrm{i}=\mathrm{nFk}{ }^{0}\left[\mathrm{c}_{0}{ }^{5} \exp \left\{-\alpha \mathrm{nF}\left(\mathrm{E}-\mathrm{E}^{0}\right) / R T\right\}-\mathrm{c}_{\mathrm{R}}{ }^{\mathrm{s}} \exp \left\{(1-\alpha) \mathrm{nF}\left(\mathrm{E}-\mathrm{E}^{0}\right) / R T\right\}\right]$
and let $F / R T=f$, overpotential $\eta=E-E^{0} \Rightarrow$ current-overpotential equation

$$
i=i_{0}[\exp (-\alpha n f \eta)-\exp ((1-\alpha) n f \eta)]
$$

e.g., real Tafel plots for $\mathrm{Mn}(\mathrm{IV}) / \mathrm{Mn}$ (III) system in concentrated acid

- At very large overpotential: mass transfer limitation

Determination of reaction rate (current) by mass transport (next Lecture)

Oh, ch. 4

## Summary of Butler-Volmer Kinetics and Useful Simplifications

1. General kinetics, applicable under all current density conditions; the general BV expression for $\eta$ (solve numerically):

$$
\begin{equation*}
i_{\text {cell }}=i_{o}\left\{\exp \left(\frac{\alpha_{a} F}{R_{u} T} \eta\right)-\exp \left(\frac{-\alpha_{c} F}{R_{u} T} \eta\right)\right\} \tag{array}
\end{equation*}
$$

2. Low polarization, facile kinetics, linearized BV approximation (explicit $\eta$ expression):

$$
\begin{equation*}
\eta= \pm \frac{i}{i_{o}} \frac{R_{u} T}{\left(\alpha_{a}+\alpha_{c}\right) F} \tag{4.53}
\end{equation*}
$$

3. High polarization, Tafel approximation (explicit $\eta$ expression):

$$
\begin{equation*}
\eta=\frac{R_{u} T}{\alpha_{j} F} \ln \left(\frac{i}{i_{o}}\right) \tag{4.54}
\end{equation*}
$$

4. Both regions, $\alpha_{a}=\alpha_{c}$ sinh simplification (explicit $\eta$ expression):

$$
\begin{equation*}
\frac{R_{u} T}{\alpha F} \sinh ^{-1}\left(\frac{i_{\mathrm{cell}}}{2 i_{o}}\right)=\eta \tag{4.55}
\end{equation*}
$$
