

Stoichiometry of Biochemical Reactions III

Today's class

- How to write overall reactions from half reactions
- Overall stoichiometry – exercise!
 - Types of biochemical reactions
 - What can be known from reaction stoichiometry

Overall reactions

1. Obtain half-reactions for an electron donor (R_d), electron acceptor (R_a), and cell formation (R_c)
2. Obtain f_s and f_e
3. Write energy and cell synthesis reactions (R_e & R_s):

$$R_e = R_a - R_d$$

$$R_s = R_c - R_d$$

4. Calculate overall reaction: $R = f_e R_e + f_s R_s$

Or, instead of Step 3 & 4, $R = f_e R_a + f_s R_c - R_d$

Oxidation of benzoate w/ nitrate as e^- acceptor, $f_s=0.40$

Step 1)

Step 2)

$$f_e = 0.60, f_s = 0.40$$

Step 3)

Step 4)

Or, by combining steps 3) & 4)

Nitrification, $f_s=0.10$

Step 1)

Step 2)

$$f_e = 0.90, f_s = 0.10$$

Step 3-4)

Information available from the stoichiometry:

when 0.13 mole of NH_4^+ (or $0.13 \times 14 = 1.82$ g $\text{NH}_4\text{-N}$) is consumed,

- How much oxygen is consumed (should be supplied)?
- How much biomass is produced?
- How much nitrate is produced?
- How much alkalinity is consumed?

Nitrification: perspective on alkalinity

$\begin{aligned} \text{Alkalinity} &= [\text{HCO}_3^-] + 2[\text{CO}_3^{2-}] + \dots + [\text{OH}^-] - [\text{H}^+] \\ \text{Carbonate alkalinity} &= [\text{HCO}_3^-] + 2[\text{CO}_3^{2-}] \end{aligned}$

If a solution does not contain any carbonate alkalinity, we may write **R** as

⇒ 0.255 eq of acidity is produced per 0.13 mole of NH_4^+ (solution pH ↓)

If a solution contains sufficient carbonate alkalinity, we may write **R** as

⇒ 0.255 eq of carbonate alkalinity is consumed per 0.13 mole of NH_4^+
(negligible change in solution pH)

Methanogenesis from wastewater, $f_s=0.08$

* Assume "waste" in water is represented as $C_8H_{17}O_3N$

Step 1)

Step 2)

$$f_e = 0.92, f_s = 0.08$$

Step 3-4)

Information available from the stoichiometry:

when $0.025 \times 175 = 4.375$ g waste is consumed,

- How much methane is produced?
- What is the composition of the biogas?
- How much biomass is produced?
- How much alkalinity is produced?

Fermentation

- Organic compound serves as both e⁻ donor and e⁻ acceptor
- In the absence of oxygen
- Sugar is converted to acid, gases, and/or alcohol

ex1) ethanol fermentation

ex2) lactic acid fermentation

Fermentation, glucose to ethanol, $f_s=0.22$

Step 1)

We want to fit fermentation, the “special case” of biochemical reaction, to our framework

Let's think about R_e , the energy production reaction

So, we may construct R_e by selecting R_d and R_a as:

Note the actual fermentation does not occur this way, but by a complex pathway to partition electrons in glucose to ethanol and CO_2 . But we can use this procedure to write up the reaction stoichiometry and also to determine the reaction free energy change (ΔG_r)

We may use the typical form of R_c

Step 2)

$$f_e = 0.78, f_s = 0.22$$

Step 3-4)

Information available from the stoichiometry:

when $0.04167 \times 180 = 7.506$ g glucose is consumed,

- How much ethanol is produced?
- How much biomass is produced?
- How much alkalinity is consumed?
