Redox reactions

Oxidation/reduction reactions

- Electron transfer reactions
 - Redox couples & half reactions
 - One component is reduced (accepts electron(s))
 - One component is oxidized (donates electron(s))

$$A + e^- \leftrightarrow A^*$$

 $B + e^- \leftrightarrow B^*$
 $B + A^* \rightarrow B^* + A$

Most natural organic compounds are (primarily) electron donors

Oxidation/reduction reactions

Most important biotic reactions

- Primary energy source
 - Cell maintenance
 - Cell growth

ex) glucose oxidation mediated by microorganisms

$$\frac{1}{4}CO_2 + H^+ + e^- \to \frac{1}{24}C_6H_{12}O_6 + \frac{1}{4}H_2O \tag{A}$$

$$\frac{1}{4}O_2 + H^+ + e^- \to \frac{1}{2}H_2O \tag{B}$$

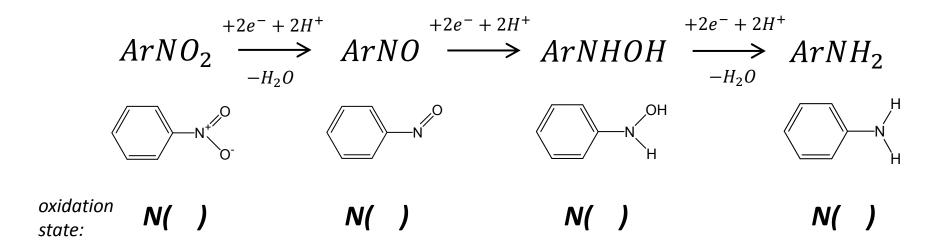

24 x [(B)-(A)]
$$C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O$$

Oxidation/reduction reactions

- Photochemical reactions
 - Will discuss later
- Redox reactions also occur abiotically in the dark
 - May involve mediators/catalysts
 - Although the reaction itself is abotic, biological molecules can be involved

Nitrobenzene reduction

- Nitrobenzene ($C_6H_5NO_2$) may be reduced in a stepwise manner to be transformed into aniline ($C_6H_5NH_2$) in the environment

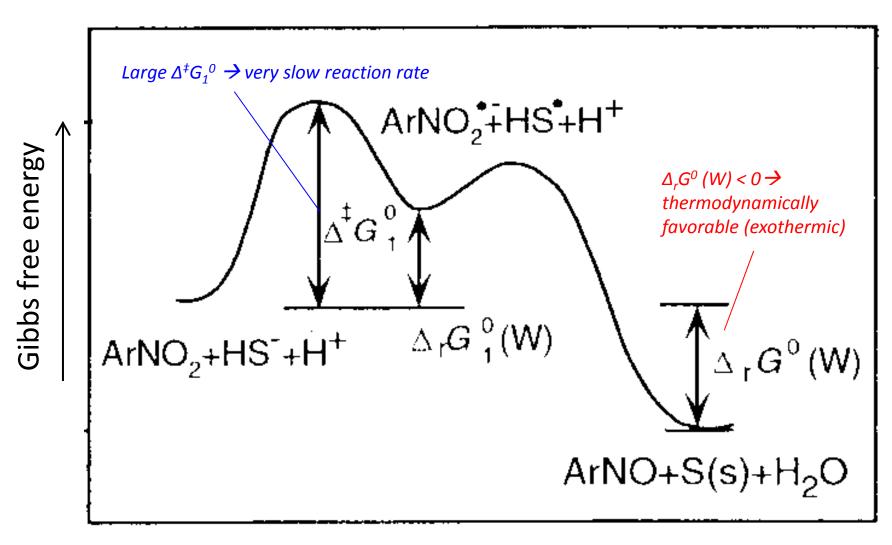

* Ar denotes C_6H_5 -

Let's consider the first step with hydrogen sulfide (H_2S) as an oxidizing compound (reductant)

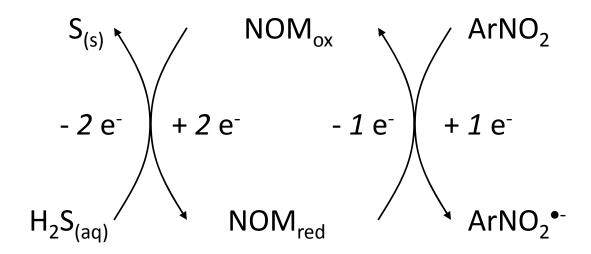

Reduction half-rxn:
$$ArNO_2 + 2e^- + 2H^+ \longrightarrow ArNO + H_2O$$

Oxidation half-rxn:
$$H_2S(aq) = HS^-(aq) + H^+ \longrightarrow S(s) + 2e^- + 2H^+$$

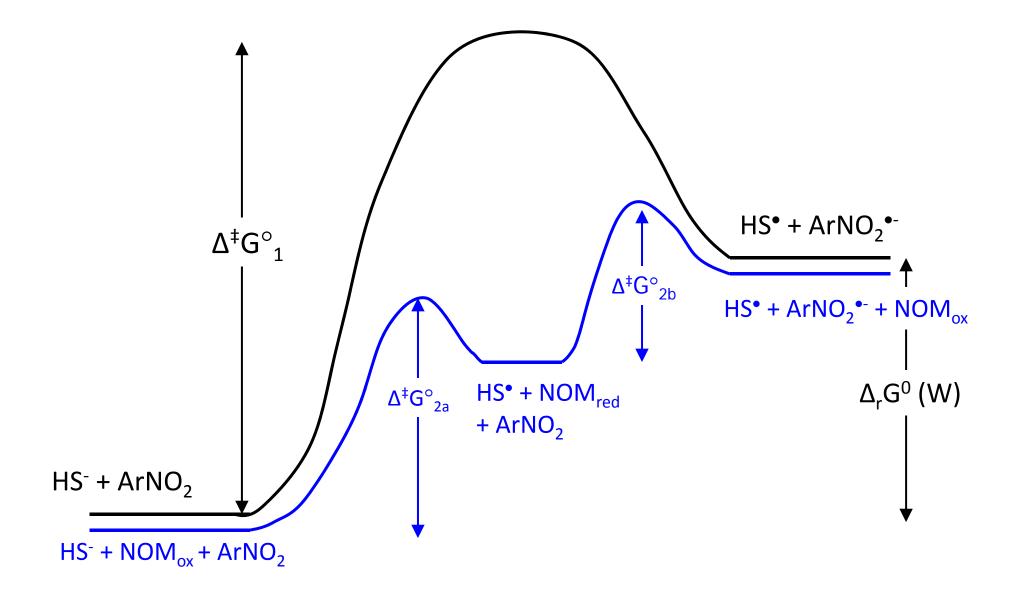

Overall rxn:
$$ArNO_2 + H_2S(aq) \longrightarrow ArNO + S(s) + H_2O$$

• Natural organic matter (NOM) acts as e⁻ transfer mediators

So ultimately electrons flow from H₂S to ArNO₂

 By e⁻ transfer by NOM, the activation energy for the rate-limiting step is reduced → reaction proceeds faster

Pd-catalyzed hydrodehalogenation

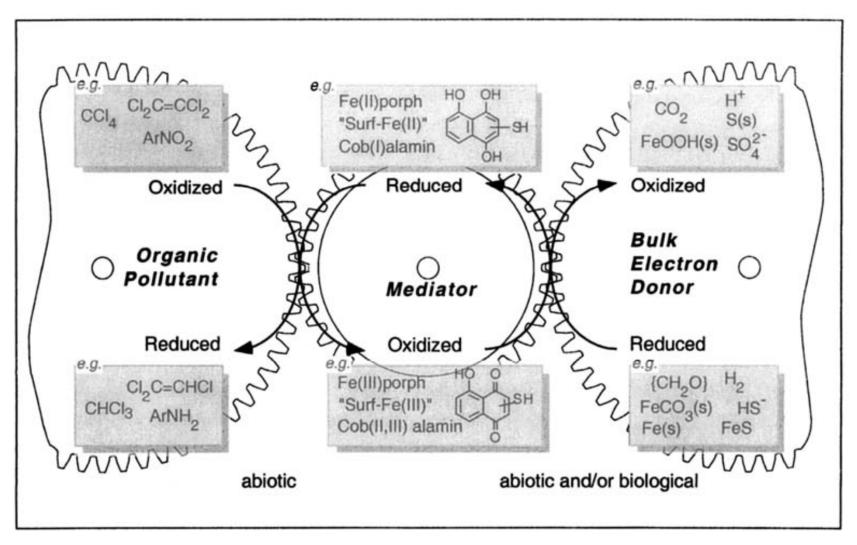

Net reaction:

$$Cl_2C = CCl_2 + 5H_2 \longrightarrow H_3C - CH_3 + 4H^+ + 4Cl^-$$
PCE ethane

- Pd dissociates H₂ molecules
- Rapid reduction of TCE at the surface of Pd

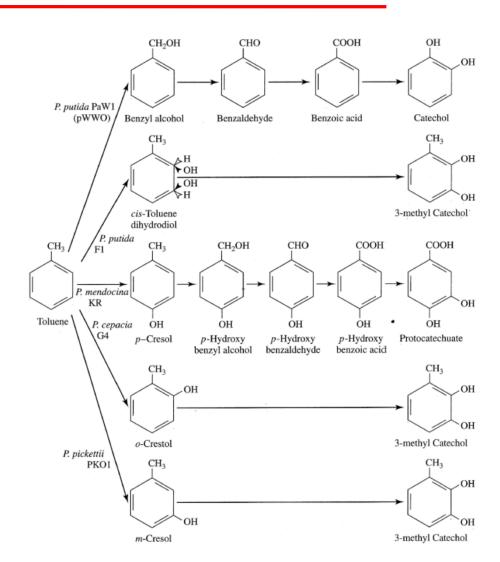

Reduction of organics by biomolecules

Redox reactions – multiple pathways

 Aerobic microbial transformation of toluene

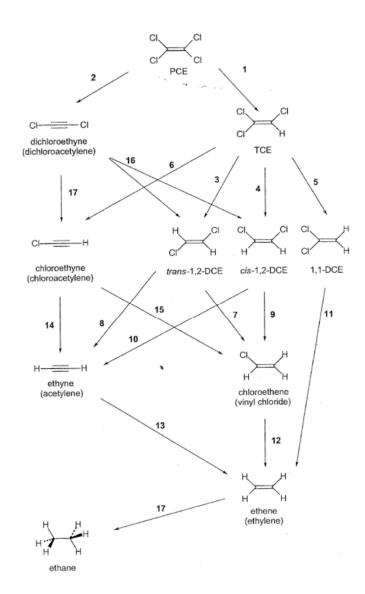

Five different aerobic biodegradation pathways for toluene, each initiated through the activity of a mono- or dioxygenase together with molecular oxygen. (Mikesell et al., 1993)

Redox reactions – multiple pathways

 Anaerobic PCE reaction pathways with zero valent iron (Fe⁰) (abiotic)

Hypothesized reaction sequence for reduction of chlorinated ethenes and related compounds by Fe⁰. Adapted from Arnold and Roberts (2000).

Redox reactions – multiple pathways

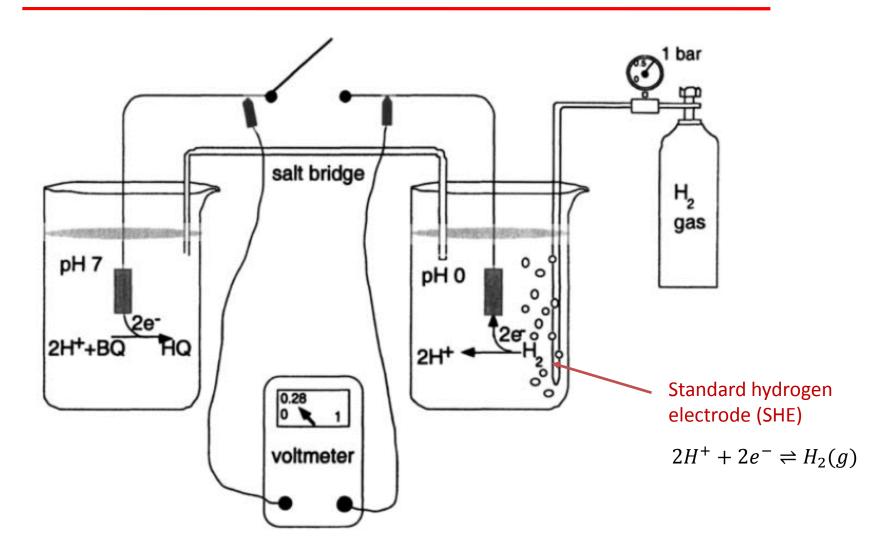

• Methanogenic TCA transformations: abiotic-biotic combination

- Thermodynamics of a redox reaction tell us if the reaction will proceed
 - If $\Delta G_r < 0$, exothermic, the reaction will proceed
 - If $\Delta G_r > 0$, endothermic, the reaction is not likely to proceed
- It is useful to prepare a list of free energy change of half reactions
 - You can pick up a pair of reduction/oxidation half reactions from the list, and then combine $\Delta G_{r \, (reduction)} \, \& \, \Delta G_{r \, (oxidation)}$ to obtain $\Delta G_{r \, (overall)}$
- How do we determine ΔG_r of half reactions by experiments?

 Consider a reversible reaction to convert 1,4-benzoquinone (BQ) to hydroquinone (HQ):

- Use reduction potentials for evaluating the free energy of the half reaction
 - Perform the reaction at the surface of an inert electrode (ex: platinum, graphite)
 - At the other side, another inert electrode is immersed in an aqueous solution maintained at pH 0 (i.e., $\{H^+\}=1$) and bubbled with molecular hydrogen $(p_{H_2}=1\ bar)$ standard hydrogen electrode (SHE)

Overall reaction:

$$BQ + H_2(g) + 2H^+ \rightleftharpoons HQ + 2H^+$$
1 bar pH=7 pH=0
(at SHE) (prev. (at SHE) example)

With half reactions:

- BQ
$$\leftrightarrow$$
 HQ electrode: $BQ + 2H^+ + 2e^- \rightleftharpoons HQ$

- SHE:
$$2H^+ + 2e^- \rightleftharpoons H_2(g)$$

Relationship between the electrical potential and the free energy

– Assuming electrochemical equilibrium at the electrode surface, then the potential difference, ΔE , is directly related to the free energy change, $\Delta_r G$ of the reaction:

$$\Delta_r G = -nF\Delta E$$

n = number of electrons transferred

= 96.5 kJ/mole-V

F = Faraday constant, 96485 Coulomb/mole

At the SHE

 We assign a zero value of electrical potential, and thus, a zero value of a standard free energy change:

$$H^{+} + e^{-} \rightleftharpoons \frac{1}{2}H_{2}(g)$$
 $\Delta E^{0} = 0 V, \quad \Delta_{r}G^{0} = 0 kJ/mol$

– Then, the electrical potential change of the half reaction, $BQ + 2H^+ + 2e^- \rightleftharpoons HQ$, can be directly measured by the electrical potential change at the galvanic cell

The electrical potential relative to SHE, E_H

$$E_H = -\frac{\Delta_r G}{nF}$$

- The E_H value for any conditions other than the "standard" state
 - The free energy change of a reaction (Δ_r G) at any conditions is given as

$$\Delta_r G = \Delta_r G^0 + RT \ln Q_r$$

$$E_H = E_H^0 - \frac{RT}{nF} lnQ_r = E_H^0 - \frac{2.303RT}{nF} logQ_r$$

 E_H^0 = standard redox potential or standard reduction potential (E_H at 25°C with unit (1) activities for all reaction components)

 Q_r = reaction quotient

for reaction aA + bB = cC + dD,
$$Q_r = \frac{\{C\}^c \{D\}^d}{\{A\}^a \{B\}^b}$$

Conditions for $E_H^0 \& E_H^0$ (W)

- E_H^0
 - All reaction components have unit activities
- $E_H^o(W)$
 - E_H under typical natural water conditions:
 - pH = 7
 - $[Cl^-] = 10^{-3} \text{ M}; [Br^-] = 10^{-5} \text{ M}$
 - Organic oxidant and reductant have unit activities

$\Delta_r G^0 \& \Delta_r G^0$ (W) and $E_H^0 \& E_H^0$ (W)

Q: Consider the half reaction in an aqueous solution:

$$2NO_3^- + 12H^+ + 10e^- \Rightarrow N_2(g) + 6H_2O$$
 (denitrification)

Calculate the E_H^0 , E_H^0 (W), and $\Delta_r G^0$ (W) values of the reaction. Initiate with the calculation of $\Delta_r G^0$ using the enthalpy of formation for each species:

$$\Delta_f G^0{}_{NO_3^-}(aq) = -111.3 \, kJ/mole$$
 $\Delta_f G^0{}_{H^+}(aq) = 0 \, kJ/mole$
 $\Delta_f G^0{}_{e^-}(aq) = 0 \, kJ/mole$
 $\Delta_f G^0{}_{N_2}(g) = 0 \, kJ/mole$
 $\Delta_f G^0{}_{N_2}(g) = -237.2 \, kJ/mole$

The overall free energy change of a redox reaction:

Reduction: EA + $e^- \rightarrow$ reduced EA $\Delta_{red}G^0$

Oxidation: ED \rightarrow oxidized ED + $e^ \Delta_{oxi}G^0$

EA + ED \rightarrow reduced EA + oxidized ED $\Delta_r G^0$

$$\Delta_r G^0 = \Delta_{red} G^0 + \Delta_{oxi} G^0$$

- Under the standard conditions:
 - Negative $\Delta_r G^0$: <u>favorable</u> reaction
 - Large $|\Delta_r G^0|$ (with $\Delta_r G^0 < 0$): strong <u>driving force</u> for the forward reaction, makes the backward reaction difficult
 - Note: this is thermodynamics, <u>NOT</u> kinetics!

Applying thermodynamics – simple example

 $\Delta G^{0}(W)/e^{-}$, kJ/mole

$$\mathbf{A} \qquad 2H^{+} + 2e^{-} \iff H_{2}(g)$$

B
$$O_2(g) + 4H^+ + 4e^- \leftrightarrow 2H_2O$$

B-2A
$$2H_2(g) + O_2(g) \leftrightarrow 2H_2O$$

$$\Delta_r G^0 = 4 \times (-78.3 - 40.0)$$

= -473.2 kJ/mole O_2

The equilibrium constant for this reversible reaction:

$$K = \frac{1}{P_{O_2} P_{H_2}^2}$$

Applying thermodynamics – simple example

Recall
$$\Delta_r G = \Delta_r G^0 + RT ln(Q_r)$$

at equilibrium,
$$\Delta_r G = 0$$
 and $Q_r = K$

Therefore,
$$K = \frac{1}{P_{O_2} P_{H_2}^2} = e^{-(\Delta_r G^0/RT)} \approx 10^{83}$$

The overall reaction will proceed to the right at any reasonable partial P of $H_2 \& O_2$

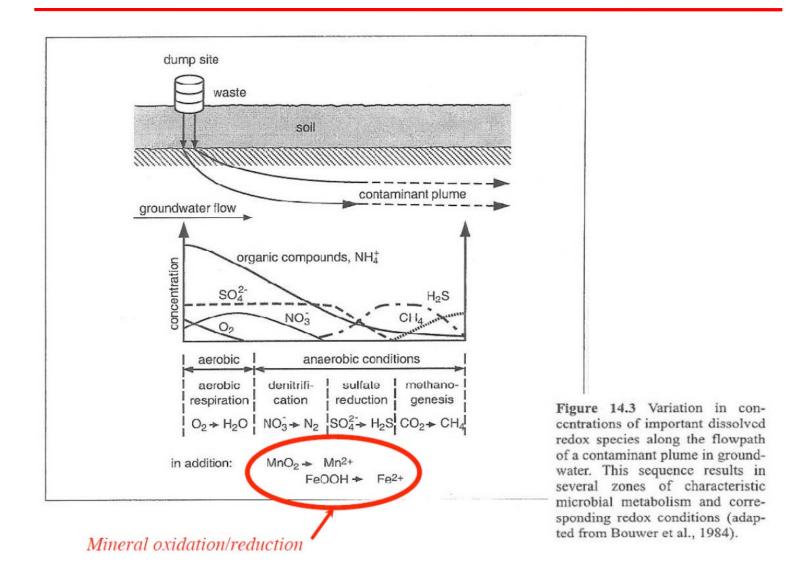

$E_H \& \Delta_r G$ of some important redox rxns

Table 14.2 Standard Reduction Potentials and Average Standard Free Energies of Reaction (per Electron Transferred) at 25 °C of Some Redox Couples that Are Important in Natural Redox Processes (The reactions are ordered in decreasing $E_{\rm H}^0(W)$ values.) ^a

	Halfreaction			Water @ pH≥7°

^a Note that most of the electron transfer reactions involving these redox couples are biologically mediated. Data from Thauer et al. (1977) and Stumm and Morgan (1995). ^b Note that these values correspond to $[HCO_3^-] = 10^{-3} M$. ^c n = number of electrons transferred.

Oxidation cascade

Oxidation cascade – why?

$$C_{6}H_{12}O_{6} + 6O_{2} \Rightarrow 6CO_{2} + 6H_{2}O$$

$$C_{6}H_{12}O_{6} + 4.8NO_{3}^{-} + 4.8H^{+} \Rightarrow 6CO_{2} + 2.4N_{2} + 8.4H_{2}O$$

$$-2714.4$$

$$C_{6}H_{12}O_{6} + 24FeOOH(s) + 24HCO_{3}^{-} + 24H^{+}$$

$$-868.8$$

$$\Rightarrow 6CO_{2} + 24FeCO_{3} + 42H_{2}O$$

$$C_{6}H_{12}O_{6} + 3SO_{4}^{2-} + 3H^{+} \Rightarrow 6CO_{2} + 3HS^{-} + 6H_{2}O$$

$$-482.4$$

$$C_{6}H_{12}O_{6} \Rightarrow 3CO_{2} + 3CH_{4}$$

$$e^{-} acceptor: CO_{2}$$

- More energy/substrate means that more of the substrate can be used to make new cells
- The electron acceptor that generates the most energy get used up first

Halogenated aliphatic hydrocarbons

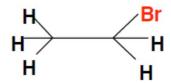

Heavily used:

- As solvents
- As pesticides
- For fire control

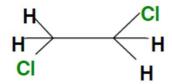

Halogens affect:

- Size
- C oxidation state

Reductive dechlorination of C₂Cl₆

Eq. (1) of Table 14.3:

$$E_H^0$$
, V $\Delta_r G^0$, kJ/mole =-nF E_H^0

$$C_2Cl_6 + 2e^- \rightarrow C_2Cl_4 + 2Cl^-$$

Couple with Eq. 11b of Table 14.2:

$$2H^+ + 2e^- \rightarrow H_2$$

0

0

Overall reaction:

$$C_2Cl_6 + H_2 \rightarrow C_2Cl_4 + 2H^+ + 2Cl^-$$

$$\Delta_r G^0 = -183.4 - 0 = -183.4 \, kJ/mole \, C_2 C l_6$$

$$\Delta_r G^0 = -RT lnK$$

$$K = e^{-\Delta_r G^0/RT} = 1.4 \times 10^{32} = \frac{[C_2 C l_4][H^+]^2 [C l^-]^2}{[C_2 C l_6] P_{H_2}}$$

Reductive dechlorination of C₂Cl₆

Using $[H^+] = 10^{-7} \text{ M} \& [Cl^-] = 10^{-3} \text{ M}$:

$$\frac{[C_2Cl_4]}{[C_2Cl_6]} = (1.4 \times 10^{52}) \times P_{H_2}$$

- For any reasonable partial pressure of H_2 , the amount of C_2Cl_6 remaining at equilibrium is infinitesimal \rightarrow Thermodynamically the reaction goes all the way to the right
- This reaction mostly occurs biologically, so the presence of microorganisms capable of transforming C₂Cl₆ is required!
 - Organic compound is used as an e- acceptor in this case
 - Note C₂Cl₆ is an anthropogenic compounds → only a limited number of species can use it!
