Lecture 10 - Transistor : 3 Legged device of semiconductor
: To give current amplification with voltage following

C (Collector), E (Emitter), B (Base)
NPN type Symbol Direction control V/V
C

Rules: (for NPN type)

1. $\mathrm{V}_{\mathrm{C}}>\mathrm{V}_{\mathrm{E}}$ (or $\mathrm{V}_{\mathrm{C}}-\mathrm{V}_{\mathrm{E}} \geq 0.2 \mathrm{~V}$ ) for flowing
2. $\mathrm{V}_{\mathrm{B}}-\mathrm{V}_{\mathrm{E}} \doteqdot 0.6 \mathrm{~V}$ when flowing
3. $I_{C}=\beta I_{B}$ where $\beta \doteqdot 100$, and $I_{E}=I_{C}+I_{B}=(\beta+1) I_{B} \doteqdot \beta I_{B}=I_{C}$

## Application:

1. Current source or current supply
: To provide constant current into circuit, regardless of $R_{\text {LOAD }}$
(1) Big R

$R_{\text {LOAD }}$
$\mathrm{i}=\mathrm{V} / \mathrm{R}_{\text {LOAD }}$

$$
\begin{aligned}
\mathrm{i} & =\mathrm{V} /\left(\mathrm{R}+\mathrm{R}_{\text {LOAD }}\right)=\mathrm{V} / \mathrm{R}\left(1+\mathrm{R}_{\text {LOAD }} / \mathrm{R}\right) \\
& \fallingdotseq \mathrm{V} / \mathrm{R}=\text { const } \therefore \text { Big } \mathrm{R}\left(\gg \mathrm{R}_{\text {LOAD }}\right) \text { needed }
\end{aligned}
$$

(2) Transistor Current Source

When $\mathrm{V}_{\mathrm{B}} \geq 0.6 \mathrm{~V}, \mathrm{~V}_{\mathrm{E}}=\mathrm{V}_{\mathrm{B}}-0.6$ and
$\mathrm{I}_{\mathrm{C}}=\mathrm{I}_{\mathrm{E}}=\mathrm{V}_{\mathrm{E}} / \mathrm{R}_{\mathrm{E}}=\left(\mathrm{V}_{\mathrm{B}}-0.6\right) / \mathrm{R}_{\mathrm{E}}$
Thus $I_{C}$ is supplied to $R_{\text {LOAD }}$ that is regardless of $R_{\text {LOAD }}$
$\therefore$ Current Source or Current Supply
2. Emitter Follower
: Current is amplified by $\beta$ times while voltage is following

$\mathrm{V}_{\text {out }}=\mathrm{V}_{\mathrm{E}}=\mathrm{V}_{\text {in }}-0.6 \quad \therefore \Delta \mathrm{~V}_{\text {out }}=\Delta \mathrm{V}_{\text {in }}$; Replica of Input voltage, where Gain $=\Delta \mathrm{V}_{\text {out }} / \Delta \mathrm{V}_{\text {in }}=1$

And $I_{E} \equiv I_{C}=\beta I_{B}$; Thus current is amplified while voltage is following.
$\therefore$ Emitter Follower

Emitter follower is to be driven or to drive a device.
Thus input impedance, $Z_{\text {in }}$, is of interest at the Vin point.
Impedance is defined as the ratio of $\Delta V$ to $\Delta I$ at any point within circuit.
$\mathrm{Z}_{\text {out }}=\mathrm{Z}_{\mathrm{E}}=\Delta \mathrm{V}_{\mathrm{E}} / \Delta \mathrm{I}_{\mathrm{E}}=\mathrm{R}$
$\mathrm{Z}_{\text {in }}=\mathrm{Z}_{\mathrm{B}} \equiv \Delta \mathrm{V}_{\mathrm{B}} / \Delta \mathrm{I}_{\mathrm{B}}=\Delta \mathrm{V}_{\mathrm{E}} /\left(\Delta \mathrm{I}_{\mathrm{E}} / \beta\right)=\beta \Delta \mathrm{V}_{\mathrm{E}} / \Delta \mathrm{I}_{\mathrm{E}}=\beta \mathrm{R}=\beta \mathrm{Z}_{\text {out }}$
As $Z_{\text {out }} \ll Z_{\text {in }}$, Emitter follower is a very nice device to drive or to be driven.

Note that very big or infinite $Z_{i n}$ is an ideal to be driven by any circuit.
Also very small or zero $Z_{\text {out }}$ is an ideal to drive any circuit.
3. AC coupled Emitter Follower

In the above Emitter Follower, TR is not active when $\mathrm{V}_{\text {in }}<0.6 \mathrm{~V}$

How to cope with the AC voltage signal for Vin? Answer is to use

1) Biasing:

To pull TR's quiescent voltage to midpoint between Vcc and GND where the quiescent voltage is when no AC signal is applied.

Then the TR becomes active, and Emitter following is possible.
$\Rightarrow A C$ signal is to ride over the pulled TR's quiescent voltage(DC)
A good method of biasing or DC offsetting is to add capacitor together with the voltage divider as follows;

Electrons from $\mathrm{V}_{\mathrm{in}}$ ac is getting into the charged capacitor, then overflown (or discharged) electrons are flowing to the voltage divider, riding over the $D C$ offset voltage given by $R_{1}, R_{2}$ voltage divider.

Thus $\mathrm{V}_{\text {in }}$ ac signal is adding to the $D C$ voltage of $\operatorname{Vcc} R_{2} /\left(R_{1}+R_{2}\right)$, then leads to $\mathrm{V}_{\text {out }}$

Note the symbol + where + sign is higher voltage (or biased) direction.

Q: $\mathrm{V}_{\text {in }}$ ac can have Impedance?
Yes. It can be a signal from a sensor that can have impedance $Z_{\text {in }}$, that is viewed from the sensor output.

Thus $Z_{\text {in }} \ll Z_{\text {TOTAL }}$ also should be checked.

## 2) DC Blocking

To remove the biased DC component from the signal by adding the blocking capacitor.

$V_{\text {in }}=V_{C}+V_{R}$ and $Z_{C}=1 / j \omega C, Z_{R}=R$
$\mathrm{V}_{\mathrm{C}}=\mathrm{V}_{\text {in }} \mathrm{Z}_{\mathrm{C}} /\left(\mathrm{Z}_{\mathrm{C}}+\mathrm{Z}_{\mathrm{R}}\right)=\mathrm{V}_{\text {in }} /(1+\mathrm{j} \omega \mathrm{RC})$
$\Rightarrow$ Low freq. part $\left(V_{C}=V_{D C}\right.$ if $\left.\omega=0\right)$
$\mathrm{V}_{\mathrm{R}}=\mathrm{V}_{\text {in }} \mathrm{Z}_{\mathrm{R}}\left(\mathrm{Z}_{\mathrm{C}}+\mathrm{Z}_{\mathrm{R}}\right)=\mathrm{V}_{\text {in }}\{j \omega \mathrm{RC} /(1+j \omega \mathrm{RC})\}$
$\Rightarrow$ High freq. part $\left(\mathrm{V}_{\mathrm{R}}=\mathrm{V}_{\text {in }}-\mathrm{V}_{\mathrm{C}}=\mathrm{V}_{\mathrm{AC}}\right.$, when $\left.\omega=0\right)$
$\therefore \mathrm{V}_{\mathrm{R}}$ is the $A C$ voltage signal after the $\mathrm{V}_{D C}$ is removed.
( Q : What happen if the sequence of $C, R$ is changed?)
This is a DC blocking capacitor or a kind of HPF with $\omega_{3 d B}=1 / R_{\text {eq }} C$
where $R_{\text {eq }}$ is the total equivalent resistor including back and forth resistors relevant to C .

Also note the symbol + for biased direction.
Ex) Design a AC coupled Emitter Follower that drives AC coupled load.

## Design Spec:

$\mathrm{Vcc}=+15 \mathrm{~V}$, TR's $\mathrm{I}_{\text {quiescent }}=0.5 \mathrm{~mA}, \mathrm{R}_{\text {LOAD }}=4.7 \mathrm{~K} \Omega, \mathrm{~V}_{\text {in }}$ is ac voltage signal from a sensor of $10 \mathrm{~K} \Omega$ input impedance. Choose $f_{3 d B}=100 \mathrm{~Hz}$
(Source: Student Manual for The Art of Electronics, Thomas C. Hayes, Paul Horowitz, Cambridge University Press, 1989)

## AC coupled Emitter Follower

1) $V_{E}$ centering in quiescence of TR

In quiescence, $\mathrm{V}_{\mathrm{E}}=15 \mathrm{~V} / 2=7.5 \mathrm{~V}$ (chosen)
Thus $\mathrm{R}_{\mathrm{E}}=\mathrm{V}_{\mathrm{E}} / \mathrm{I}_{\text {quiescence }}=7.5 / 0.5 \mathrm{E}-3=15 \mathrm{~K} \Omega$
$V_{B}=7.5+0.6($ Diode drop $)=8.1(\mathrm{~V})$
(1) DC component

When quiescence, Voltage divider gives
$V_{B}=V_{C c R} /\left(R_{1}+R_{2}\right)$, thus $8.1 / 15=R_{2} /\left(R_{1}+R_{2}\right) \quad$ eq(1)
When quiescence, the voltage divider should drive the circuit below $B$,
Thus $R_{1} \| R_{2} \ll Z_{B}$ and $Z_{B}=\beta\left(R_{E} \| \infty\right)=\beta R_{E}$
$\therefore R_{1} R_{2} /\left(R_{1}+R_{2}\right)=Z_{B} / 10=10(15)=150 \mathrm{~K} \Omega$ eq(2)
From eq(1),(2); $\mathrm{R}_{1}=277 \mathrm{~K} \Omega$ and $\mathrm{R}_{2}=325 \mathrm{~K} \Omega$

## (2) AC component

For the ac signal, the DC component is added by the biasing circuit; and removed by the blocking capacitor, respectively. Thus we need a DC blocking capacitor (or a kind of HPF passing over 100 Hz ), to block the $D C$ component, and the relevant $R_{e q}=R_{E} \| 0+R_{\text {LOAD }}=4.7 \mathrm{~K}$

This is a kind of Cascaded HPF, and $\omega_{3 \mathrm{~dB}}$ adjustment is needed to prevent excessive attenuation near the $\omega_{3 \mathrm{~dB}}$ frequency range. Thus $\omega_{3 \mathrm{~dB}}$ can be adjusted such as $\omega 1_{3 d B}=\omega_{3 d B}=100 \mathrm{~Hz}$ and $\omega 2_{3 d B}=\omega_{3 d B} / 3=33 \mathrm{~Hz}$ For the DC blocking capacitor, $\omega 2_{3 d B}=(2 \pi)(100 / 3)=1 / R_{\text {eq }} C_{2}$
$\therefore C_{2}=1 /\{2 \pi(33)(4700)\} \div 1 \mu \mathrm{~F}$ from the commercial choice
For the biasing circuit, $\omega 1_{3 \mathrm{~dB}}=(2 \pi)(100 \mathrm{~Hz})=1 / \mathrm{R}_{\text {TOT }} \mathrm{C}_{1}$
where $R_{\text {TOT }}$ is the total resistance relevant for $C_{1}$.
$R_{\text {TOT }}=10 K+R_{1}\left\|R_{2}\right\| \beta\left(R_{E} \| R_{\text {LOAD }}\right)$ and $R_{E} \| R_{\text {LOAD }}=(15)(4.7) /(15+4.7)=3.58 K \Omega$
As $\mathrm{R}_{1} \| \mathrm{R}_{2}=150 \mathrm{~K} \Omega$, thus $\mathrm{R}_{\text {TOT }}=10 \mathrm{~K}+(150)(358) /(150+358)=115.7 \mathrm{~K} \Omega$
Thus $C_{1}=1 /\{(115.7)(2 \pi)(100)\} \doteqdot 0.02 \mu \mathrm{~F}$

Quick check for $Z_{\text {in }}(=10 \mathrm{~K} \Omega) \ll Z_{\text {emitter follower }}(=105.7 \mathrm{~K} \Omega)$ and it is $O K!!$
Thus design is completed for the AC coupled Emitter follower.

HW7) Design a AC coupled Emitter follower such that
$V_{c c}=+12 \mathrm{~V}$, TR's $I_{\text {quiescent }}=0.5 \mathrm{~mA}, \mathrm{R}_{\text {LOAD }}=10 \mathrm{~K} \Omega, \mathrm{~V}_{\text {in }}$ is ac voltage signal from a sensor of $10 \mathrm{~K} \Omega$ input impedance. Choose $f_{3 d B}=100 \mathrm{~Hz}$ and use alternative method for preventing excessive attenuation at $\omega_{3 \mathrm{~dB}}$
